Exercise 1. Let $d \geq 1$ and $m > 2$ be integers, and let us consider the following process on $S = \{0, \ldots, m-1\}^d$: at each step, from state $x \in S$, pick a component of $x$ uniformly at random and change it to another number in $\{0, \ldots, m-1\}$, chosen again uniformly at random.

a) Write down the transition matrix $P$ of this chain. Is this chain is ergodic? What is its stationary distribution? Is the detailed balance equation satisfied?

It turns out that the eigenvectors of $P$ are given by $\phi(z), z \in S$, where

$$
\phi_x(z) = \exp(2\pi i x \cdot z/m), \quad x \in S,
$$

and $x \cdot z = \sum_{j=1}^d x_j z_j$.

b) Compute the corresponding eigenvalues $(\lambda_z, z \in S)$ of $P$.

*Hint:* Express these in terms of $|z| = \#\{\text{non-zero components of } z\}$.

c) Deduce the value of the spectral gap for $d > 2$, as well as a corresponding upper bound on $\|P^n_0 - \pi\|_{TV}$.

d) Compare this upper bound to the general lower bound found in class. Do these two bounds match for large $m$ and $d$?

e) Through a more careful analysis, find a tighter upper bound on $\|P^n_0 - \pi\|_{TV}$ for large $m$ and $d$.

Exercise 2. Regarding the lazy random walk on $\{0,1\}^d$, we saw in class that $\|P^n_0 - \pi\|_{TV}$ is arbitrarily close to 1 for

$$
n = \frac{d+1}{4} (\log d - c)
$$

and $c > 0$ arbitrarily large. Following the reasoning made in class (but the technique is simpler here!), show that the following distance:

$$
\|P^n_0 - \pi\|_2 = \left( \sum_{y \in \{0,1\}^d} \left( \frac{p_{0y}(n)}{\sqrt{\pi_y}} - \sqrt{\pi_y} \right)^2 \right)^{1/2}
$$

can be made arbitrarily large by taking again $n = \frac{d+1}{4} (\log d - c)$ and $c > 0$ arbitrarily large.

*NB:* The above distance is the $\ell^2$-distance between $P^n_0$ and $\pi$; it has been shown in class to be an upper bound on $\|P^n_0 - \pi\|_{TV}$ (with an extra factor 2).
